March 25, 2026

Abstract

CIFAR-100 from scratch (compact SE-ResNet): Stage A → Stage B (**65.17%** test) → Stage C with Mixup/CutMix/EMA (**68.14%** test). Evaluation uses `results.py`.
Public repository: https://github.com/Rex-Yim/CIFAR100Classification.

1 Introduction

We train on CIFAR-100 without pretrained weights (Colab; checkpoints on Drive) and report test accuracy via the course `results.py` script.

Code and repository. All implementation code, shell pipelines, Colab helpers, and LaTeX sources for this report and the companion slides are maintained in the public GitHub repository https://github.com/Rex-Yim/CIFAR100Classification (default branch `main`).

2 Dataset

CIFAR-100: 50,000 train / 10,000 test. Per-channel normalization uses $\mu = (0.5071, 0.4867, 0.4408)$ and $\sigma = (0.2675, 0.2565, 0.2761)$. Stages B/C hold out 10% stratified validation (seed 42); Stage A uses all training images and evaluates on the test set each epoch.

3 Methodology

3.1 Model Architecture

SE-ResNet (`se_resnet`): SE attention, `base_width` = 32, two blocks per stage (2×2×2×2), GAP, linear to 100 classes.

3.2 Training Strategy

- **Stage A:** 4 epochs, basic aug, SGD lr 0.1, warmup 1, cosine; test each epoch; ∼33% checkpoint for init.
- **Stage B:** `--init-from`; RandAugment (N=2, M=9), erasing 0.05, label smooth 0.05, SGD lr 0.05, warmup 5, 30 epochs; val for selection; test via `results.py`. No EMA.

- **Stage C:** From Stage B `best.pt`, 30 epochs (`scripts/iterate_from_stageb_stage_c_mixema.sh`), RandAugment, Mixup/CutMix, lr 0.015, warmup 3, batch 128, clip 1, EMA 0.999. Select by val accuracy.

Code: `train.py`, `model.py`, `utils.py`; Stages A–B via `scripts/quick_se_resnet_results.sh`; Stage C via Colab/`scripts/iterate_from_stageb_stage_c_mixema.sh`. AMP on CUDA. Best test from `results.py` on Stage C `best.pt`.

4 Experiments

4.1 Experimental Setup

Table 1 summarizes Stages A–C; Table 2 reports accuracy.

Table 1: Hyperparameters for the SE-ResNet pipeline (Stages A–B) and Stage C improvement.

Setting	Stage A	Stage B	Stage C
Epochs	4	30	30
Batch size	64	256	128
Augmentation	Basic (crop, flip)	RandAugment + erasing	RandAugment + erasing
Mixup / CutMix	None	None	Both (α 0.2 / 1.0, p=0.5)
EMA	No	No	Yes (0.999)
Optimizer	SGD (momentum 0.9, WD 5×10^{-4})	Same	Same
LR schedule	Warmup 1 + cosine	Warmup 5 + cosine	Warmup 3 + cosine
Initial LR	0.1	0.05	0.015
Label smoothing	0	0.05	0.05
Eval during training	Test (10,000)	Val (10% of train)	Val (10% of train)

4.2 Results

Table 2: CIFAR-100 accuracy. Official test numbers are from `results.py` on the listed checkpoint.

Stage	Metric	Value
A: baseline (4 epochs)	Test accuracy	$\approx$ 33.3%
B: finetune (30 epochs)	Best validation	65.22%
B: finetune	Official test (Stage B `best.pt`)	65.17%
C: from Stage B (30 epochs)	Best validation	68.48%
C: from Stage B	**Official test** (Stage C `best.pt`)	**68.14%**

Stage B validation and test agree ($\sim$65.2%). Stage C reaches best validation 68.48% (epochs 29–30) and **68.14%** official test, indicating that Mixup/CutMix and EMA help when starting from the Stage B weights.

4.3 Training curves and log summary

Figure 1 summarizes per-epoch behavior for Stages A–C. Stages A–B follow the run in Table 2: Stage A on the official test each epoch; Stage B on train and validation (90%/10% split). Stage C plots train and validation under Mixup/CutMix and EMA—**train** accuracy here is not

directly comparable to clean accuracy; use the validation curve and Table 3 (right) for Stage C selection.

Figure 1: Per-epoch accuracy for Stages A–C (shared y-axis 0%–100%). *Left:* Stage A, official test. *Center:* Stage B, train vs. validation. *Right:* Stage C, train vs. validation (mixed batches). Logs: `artifacts/colab_training_log_4epoch_plus_30_to_65pct.txt` (Stages A–B), `artifacts/stage_c_training_history.json` (Stage C). Script: `scripts/plot_training_curves.py`.

Epoch logs (Stages A–C). Subtables (a)–(c) in Table 3 list selected epochs (full JSON for Stages A–B in the Colab artifact; Stage C in `artifacts/stage_c_training_history.json`). Stage B best validation 65.22% at epoch 28. Stage C best val 68.48% (epochs 29–30); official test **68.14%** via `results.py`.

(a) Stage A (baseline): test accuracy per epoch.

Epoch	Test
1	9.12%
2	17.50%
3	24.33%
4	33.32%

(b) Stage B (finetune): selected epochs. Best val 65.22% at epoch 28.

Ep.	Train	Val
1	25.44%	36.40%
5	30.29%	39.46%
10	39.18%	49.46%
15	46.24%	53.98%
20	52.52%	60.02%
25	57.93%	63.80%
28	60.06%	65.22%
30	61.06%	65.16%

(c) Stage C (`sota_se_resnet_exp1`): validation accuracy.

Ep.	Val
1	65.38%
10	65.90%
20	67.58%
25	68.32%
28	68.40%
29	68.48%
30	68.48%

Table 3: Per-epoch training logs for Stages A–C (subtables left to right).

4.4 Interactive web demo

We ship a small FastAPI app under `demo/` (`demo/app.py`): a browser UI to upload an image or use shipped CIFAR-100 32×32 crops, then view top-k softmax probabilities for the same SE-ResNet checkpoint as in evaluation. It runs **locally** (e.g. `uvicorn demo.app:app`) and is for qualitative inspection only; official numbers still come from `results.py`.

(a) Browser UI (local server).

(b) Two crops from `demo/static/samples/`: highest vs. lowest top-1 confidence among shipped PNGs (generated with `scripts/render_demo_slide_panels.py`).

Figure 2: Optional local demo for qualitative behavior (not used for grading metrics).

5 Discussion

- **Initialization matters:** Starting from the Stage A weights gave a large jump over training the finetune recipe from scratch in the same wall-clock budget.
- **RandAugment + longer schedule:** Stronger augmentation and more epochs on top of the Stage A baseline outperformed a larger Wide-ResNet trained from scratch in the same time budget.
- **Stage C on top of Stage B:** Treating the ∼65% model as a *base* checkpoint and finetuning with Mixup, CutMix, and EMA at a lower learning rate yielded ∼3 percentage points on official test (65.17% → 68.14%), with best validation 68.48%.
- **Trade-offs:** The SE-ResNet path is faster to iterate than a full Wide-ResNet Hydra ladder; the cost is a lower ceiling than very large models trained for hundreds of epochs on CIFAR-100.

6 Contribution

Rex Yim led implementation: data pipeline, preprocessing and augmentation experiments, model code, training and checkpoints, analysis, and primary drafting of this report and slides. Early drafting used OpenAI Codex; later work used Cursor. Stages B and C ran on Google Colab (NVIDIA GPU).

Jason Chen contributed brainstorming, discussions on preprocessing and training schedule (including epoch sizes), and support for presentation preparation and Q&A practice.

7 Conclusion

We trained a compact SE-ResNet on CIFAR-100 (Stages A–B), then improved it with Stage C (Mixup, CutMix, EMA) from the Stage B checkpoint. The best official test accuracy is **68.14%** (`results.py`), with Stage B alone at **65.17%**. Future work could use longer schedules or wider models if compute permits.
